

# All About Sparrows

Sparrows are small, lively birds that are found all over the world. They live in cities, villages, forests, and farmlands. Sparrows are known for their cheerful chirping sounds and their ability to adapt to many different places. They are very social birds and often gather in small groups called flocks.

Sparrows eat mostly seeds, grains, and small insects. They use their small, strong beaks to pick up food from the ground or plants. Sparrows are active during the day, which makes them diurnal birds. They are excellent at flying short distances and can quickly escape from predators like cats or larger birds.

Baby sparrows are called chicks. They are born in nests made of twigs, leaves, and feathers, which their parents carefully build. The parents feed the chicks until they are strong enough to fly and find food on their own. Sparrows are important for nature because they help spread seeds and control insect populations.

Sparrows face dangers from humans and changes in the environment. Cutting down trees and buildings in cities can destroy their homes. Wildlife groups encourage people to protect birds and plant more trees. Protecting sparrows helps keep cities and forests full of life and healthy.

Where do sparrows live?

---

What do sparrows eat?

---

What are baby sparrows called?

---

Are sparrows active during the day or night?

---

Why do sparrows need protection today?
